## ABSTRACT

Seston samples from eight lakes lying within the Trent River Drainage Basin, located in central Ontario, were characterized with respect to three nitrogen fractions, three phosphorus fractions, organic carbon, phytoplankton content and chlorophyll a.

Significant direct positive relationships were found to exist between each of the nutrient parameters and the algal biomass. Non-labile nitrogen or phosphorus to biomass ratios - mg.N<sub>3</sub> :cm<sup>3</sup> algae - 7.3:1; mg P<sub>3</sub>:cm<sup>3</sup> algae - 0.6:1; mg N<sub>3</sub>: mg chlorophyll a - 6.7:1; mg P<sub>3</sub>: mg chlorophyll a - 0.6:1 - showed close agreement with similar ratios obtained with samples from a previous study in the Bay of Quinte.

## INTRODUCTION

Phosphorus and nitrogen requirements of phytoplankton both in natural systems and laboratory cultures have been assessed on the basis of chemical analyses of the associated suspended solids or seston. Inasmuch as algae can accumulate phosphorus, and perhaps nitrogen, in excess of their immediate needs, this approach may yield misleading information in estimating the critical nutrient requirements of these organisms.

A technique described by Fitzgerald and Nelson (1966) to characterize the essential phosphorus content of algae was applied to samples of seston obtained during a study of the Bay of Quinte (Christie, 1972b). Results from the Quinte investigation illustrated a close agreement when compared to the various nutrient:biomass ratios as reported by several authors (Mullin *et al*, 1962; Strickland, 1960; Vollenweider, 1970).

Seston samples analyzed in the following investigation, obtained during an examination of nutrient-phytoplankton relationships of eight lakes lying within the Trent River Drainage Basin (Christie, 1968), were assayed to determine whether relationships obtained with materials from the Bay of Quinte also exist in other freshwater environs of Ontario.

## MATERIALS AND METHODS

The suspended solids or seston materials analyzed in this study are identical to the materials employed to characterize the standing crops of phytoplankton of the trophogenic waters of eight lakes which lie in the Trent River Drainage Basin of Southern Ontario as reported by Christie, (1968).

Initial concentration of this material for phytoplankton enumeration, previously described in the above report and more recently by Christie, (1972a) involved treatment of the raw water with mercuric chloride followed by concentration using a Sedgwick-Rafter sand filter funnel (acid washed sand). Raw water volumes of 1000 ml or 500 ml were concentrated to a final volume of 25 ml. Procedures involved in the preparation of a 5.0 ml aliquot of seston concentrate for carbon, nitrogen and phosphorus analyses have been described previously in some detail (Christie, 1972b).

In this report the carbon, nitrogen and phosphorus content of untreated aliquots of concentrate are indicated as  $C_p$ ,  $N_1$  and  $P_1$  respectively. The quantities of nitrogen and phosphorus associated with the suspended materials after centrifugation and distilled water rinsing are indicated by  $N_2$  and  $P_2$ . Parameters  $N_3$  and  $P_3$  represent the nitrogen and phosphorus quantities of concentrates after isolation by centrifugation, resuspension in a nitrogen-phosphorus free mineral media followed by a one hour boiling water bath treatment (Fitzgerald and Nelson, 1966).

Statistical analyses of the data followed procedures outlined by Snedecor and Cochran (1957).

Duplication of analyses of the nitrogen and phosphorus content of concentrates of 45 samples ( $N_1$ ,  $P_1$ ) indicated no significant difference to exist between replicates at the 95 percent level of confidence.

## RESULTS

### PHYTOPLANKTON: QUANTITY AND COMPOSITION

The phytoplankton content of water samples representing the trophogenic zone of each of eight lakes which lie within the Trent River Drainage Basin - Kushog (K), Twelve-mile (T), Balsam (B), Gull (G), Sturgeon (S), Buckhorn (Bu), Clear (C), Rice (R) - previously reported in terms of areal standard units (Christie, 1968), are displayed in Figure 1 on the basis of parts per million by volume ( $\text{cm}^3 \cdot \text{m}^{-3}$ ) and chlorophyll  $a$  ( $\text{mg} \cdot \text{m}^{-3}$ ) uncorrected with respect to phaeophytin content.

In Figure 2 the composition of the various standing crops of phytoplankton, based on  $\text{cm}^3 \cdot \text{m}^{-3}$ , indicate the predominant presence of Bacillariophyta, made up primarily of such forms as *Asterionella*, *Fragilaria*, *Melosira*, *Synedra* and *Tabellaria*. A detailed listing of the phytoplankton noted in samples from each lake have been reported elsewhere (Christie, 1968).

The relationship between the two biomass parameters was examined using all the chlorophyll data (63 observations) and the algal biomass values of equivalent samples. This analyses yielded a positive linear relationship significant at the 99.5 percent level with a dependent variable sample standard error ( $S_{\bar{y}.x}$ ) of 0.3516: Chlorophyll  $\underline{a}$  ( $\text{mg}\cdot\text{m}^3$ ) = 0.1330 (10) + 0.6562 ( $\text{cm}^3\cdot\text{m}^{-3}$ ).

## **SESTON NUTRIENTS AND PHYTOPLANKTON**

The nutrient contents of seston samples from all the lakes after various treatments - phosphorus ( $P_1, P_2, P_3$ ), nitrogen ( $N_1, N_2, N_3$ ), and carbon ( $C_p$ ) - were compared to corresponding estimates of the standing crops of phytoplankton expressed as parts per million by volume ( $\text{cm}^3\cdot\text{m}^{-3}$ ) or as chlorophyll  $\underline{a}$  ( $\text{mg}\cdot\text{m}^{-3}$ ) (Figures 3, 4, 5). Statistical testing between these data in each instance yielded a direct positive relationship with all but two cases being significant at the 99.5 percent level ( $P = 0.005$ ).

The mean, range and number of observations associated with each nutrient fraction are presented in Table II as are also the two biomass parameters.

From substitution of the biomass mean value in each equation, a corresponding dependent variable value was determined. The various nutrient quantity biomass ratios displayed in Table III were calculated by dividing the estimated nutrient value by the mean of the biomass parameter.

## DISCUSSION AND CONCLUSION

Relationships between phytoplankton development and their carbon, nitrogen and phosphorus requirements have been examined by determining the nutrient contents of seston samples both from natural environs and laboratory cultures. Based on the latter method, the minimum phosphorus requirement for several species of phytoplankton has been reported to range from 0.2 - 0.6 mg:cm<sup>3</sup>. (Vollenweider, 1970). Carbon:biomass ratios according to Mullin *et al* (1962) were found to vary from 30 - 250 mg C:cm<sup>3</sup>, being dependent on cell size. Suggested ratios between seston phosphorus, nitrogen, carbon and chlorophyll a (wt:wt) are 0.75 mg P, 7 mg N, 30 mg C per mg chlorophyll a (Strickland, 1960).

Of the various nutrient:chlorophyll a ratios obtained in this study (Table II), as determined from the regression equations based on data of Figures 3, 4, 5, the ratios mg P<sub>3</sub>: mg chlorophyll a and mg N<sub>3</sub>:chlorophyll a with values of 0.6:1 and 6.7:1 are very similar to those suggested by Strickland (1960) whereas the observed carbon:chlorophyll a ratio - 214 mg C: mg chlorophyll a - is about seven fold greater.

On the other hand, the ratio of 226 mg Cp:cm<sup>3</sup> does fall within the range reported by Mullin *et al* (1962) as does the ratio between the most tightly bound seston phosphorus fraction versus biomass (0.6 mg P<sub>3</sub>:cm<sup>3</sup>) to the range of values for the minimum phosphorus requirements per unit biomass volume, 0.2 - 0.6 mg P:cm<sup>3</sup> (Vollenweider, 1970). The phosphorus associated with the P<sub>3</sub> fraction is, therefore, considered to approximate the essential phosphorus requirement of the associated phytoplankton biomass. While no comparative data are available with respect to the minimum nitrogen requirement per unit volume of algal biomass, the closeness of the

observed ratio  $N_3$ :chlorophyll a to the ratio suggested by Strickland (1960) would suggest that the  $N_3$  nitrogen may represent the minimum nitrogen requirement per unit biomass volume.

Relationships between the nutrient contents of the seston and associated phytoplankton of samples from the Bay of Quinte have been reported previously (Christie, 1972b). Collection and handling of samples were identical in both the Quinte study and the present investigation.

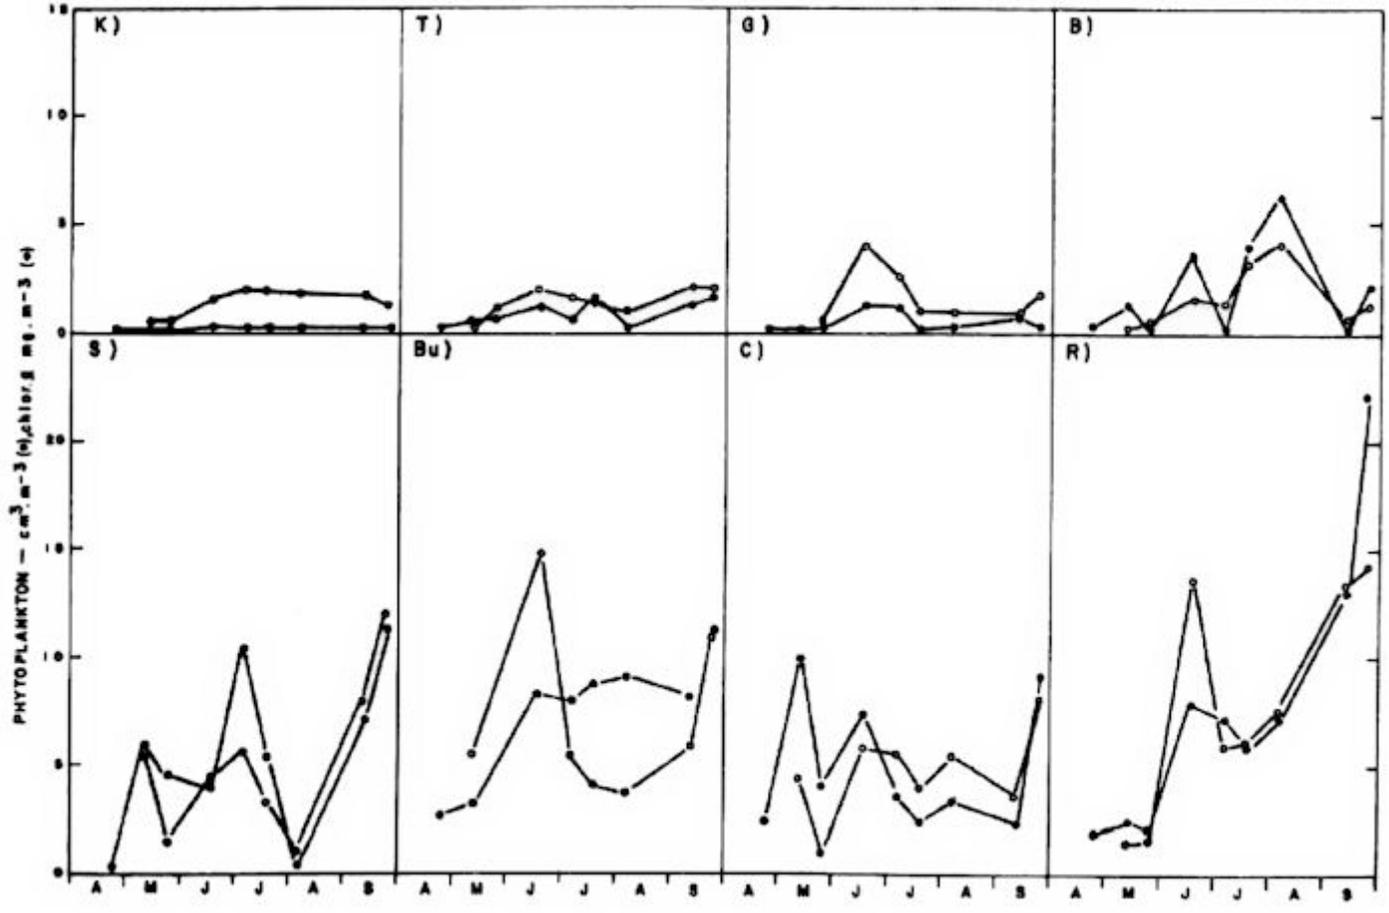

From the results of the Bay of Quinte study, positive linear relationships were found to occur between the data representing the various seston nutrient fractions versus the phytoplankton biomass, all being significant at the 99.5 percent level. In this study data representing similar fractionation of the seston nutrients when compared to associated biomass parameters also yielded a positive linear relationship in each case although some variation in the degree of significance is evident. (Figures 3, 4).

In Table III, nutrient biomass ratios calculated from the appropriate regression equations of both the present and the Quinte study are presented for comparative purposes. Although, for example, the total seston phosphorus to biomass ratios ( $P_1$ :biomass) show some variation, close agreement is evident between the ratios representing the most tightly bound phosphorus moiety versus biomass ( $P_3$ :biomass). A similar type of relationship is evident with respect to the  $N_1$ :biomass to  $N_3$ :biomass ratios from the two studies.

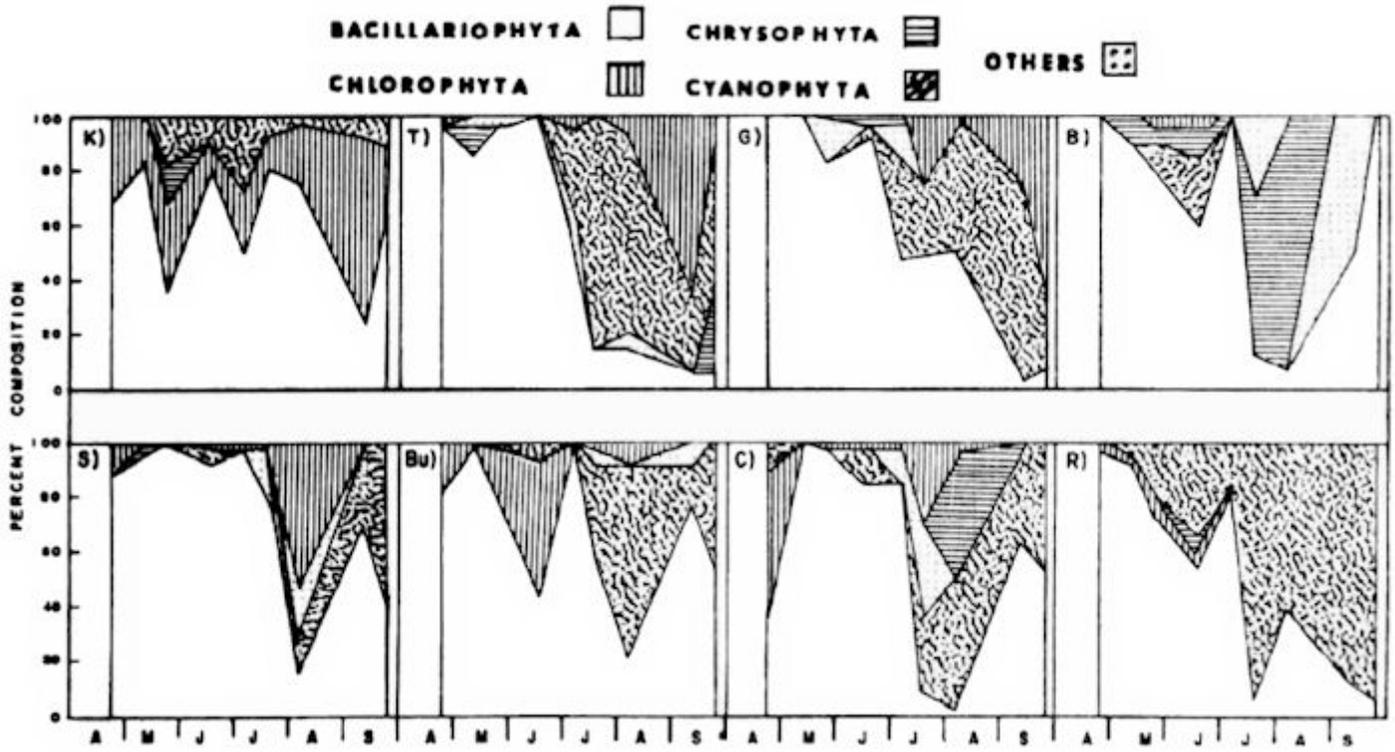

The values displaying the widest degree of variation between the two investigations are the carbon:biomass ratios. Perhaps, considering the diverse nature of the phytoplankton populations involved, in the present investigation (Figure 2) as compared to phytoplankton populations of the Bay of Quinte, which consisted predominantly of Bacillariophyta and Cyanophyta (Christie, 1972b), this type of variation should not be considered surprising. Both carbon:cm<sup>3</sup> values do fall, however, within the range of 30 - 250 mg C:cm<sup>3</sup> noted by Mullin *et al* (1962).

The close agreement of the results of this study with various published nutrient:biomass ratios and with the findings obtained from the Bay of Quinte investigation indicate that such relationships are more than just a local phenomenon of one particular Ontario freshwater environ.
